

Exploring Cross Sectional Data: The Comparative Health and Health Spending of Nations

1 Introduction

In this unit we explore the nature of cross-sectional data, which means observations of different “units” at the same point in time, in this case the set of 30 OECD countries in a given year.

An excellent resource for international comparative health data is the Organization of Economic Cooperative Development. The OECD is a public body that collects and analyzes primarily economic data for 30 relatively advanced economies. For the purposes of the assignment on this topic we will access a subset of the OECD health data using gretl.

2 The assignment

Your report should be done as a Word document. Tables and graphs should be clearly labeled. The specifics of organization of the material, textual answers to the questions asked and placement of the graphs in the final document are left to your discretion. Grading will be based on completeness, clarity, neatness and presentation value.

1. Download the 1998 OECD data file, `OECD1998.gdt`. This is available from “Other documents” folder on the class website.
2. **Make a table** containing the variables total health expenditure per capita (`hexp98`) and GDP per capita (`gdppc98`). Sort the data by `gdppc98`. Find the mean and median for each series. Display this as Table 1 in your report, and answer the following questions in relation to the table:
 - (a) Which countries have the highest and the lowest GDP per capita?
 - (b) Which countries have the highest and the lowest health expenditure per capita?
 - (c) Where does the U.S. stand in relation to the mean and median values of these variables?
3. **Make an X-Y graph** with GDP per capita on the X axis and health expenditures per capita on the Y axis. Display this as Figure 1 in your report and answer the following questions about it:
 - (a) Interpret the scatter plot and the estimated regression line. What does it say about the estimated relationship and the explanatory value of GDP in predicting a country’s level of spending on health?
 - (b) What countries are the most obvious “outliers?” Try to explain this.
 - (c) What other variables would you want to include in an investigation of a country’s total health spending, besides per-capita GDP?
4. **Make a table** including the following variables
 - § Total Expenditures on Health per capita (`hexp98`)
 - § life expectancy of the total population at birth (`lexp98`)
 - § Practicing Physician Density/1000 pop (`phys98`)

Sort the table in order of life expectancy. Find the mean and median for each series. Display this as Table 2 in your report and answer the following:

- (a) Which countries have the highest and lowest life spans?
 - (b) Who has the highest and lowest number of physicians?
 - (c) Who has the highest and lowest health spending?
 - (d) Where does the U.S. fall in relation the means of these series?
5. **Make an X-Y graph** with health spending (`hexp98`) as the X variable and life expectancy (`lexp98`) as Y. Display this as Figure 2 in your report and answer the following:
- (a) Taken at face value, what does the line of best fit suggest? For instance, how many extra years of life expectancy are gained per \$1000 per capita spent on health? (The unit is dollars per capita, so you'll need to multiply the slope by 1000.)
 - (b) What life expectancy does the equation predict for a country that spends nothing on health?
 - (c) Any comment on Turkey?
 - (d) Does this relationship seem to be linear? If not, what sort of shape might fit better?
6. **Make an X-Y graph** with health spending (`hexp`) as the X variable and infant mortality (`infm`) as Y. Display this as Figure 3 in your report and answer the following:
- (a) Describe the relationship shown in the graph.
 - (b) The relationship does not seem to be linear. Try to explain why one would not really expect it to be linear.
 - (c) Comment on the position of the U.S. in the distribution (here it might help to create a table too).
7. **Make two more X-Y graphs** This time you have a free choice: select any two pairs of variables from the datafile that you think might reveal interesting relationships. Think in terms of cause and effect relationships: select for the X axis a variable that you think may have a causal influence on your Y-axis variable. In each case, display the graph and give an account of what it shows. Also pull up the corresponding regression model and comment on the statistical significance (or not) of the relationship. Are there any surprises? Do any particular countries stand out as exceptional?
- Just in case you're stumped, here are some possible questions that could guide your selection: Do more doctors seem to translate into longer life or lower infant mortality? More nurses? What about medical technology? How closely does health spending relate to the prevalence of high-tech medical equipment? Is there a clear relationship between high-tech equipment and health outcomes such as life expectancy?
- Important note:** Some of the variables in the file are not so easy to interpret, or are difficult to compare across nations. For details on the variables, please see `OECDdefs.pdf` in the "Other documents" folder.
